I. SUMMARY

Allotropia virgata occurs primarily west of the Cascade and Sierra Nevada mountains from British Columbia to northern California. Disjunct populations occur in southwestern Montana and adjacent Idaho. The plant is a Region 1 sensitive species and is ranked G4/S1 in both Montana and Idaho. The first record of the species from Montana was in 1974. Subsequent survey work has located 27 populations in southwestern Montana on the Beaverhead, Bitterroot and Deerlodge national forests, including some timber sale blocks.

In Montana, Allotropia virgata populations occur most often in Abies lasiocarpa/Xerophyllum tenax or Abies lasiocarpa/Vaccinium scoparium habitat types. The dominant canopy tree is usually Pinus contorta with Pseudotsuga menziesii often co-dominant. Stand age is 120-330 years with an average of about 200 years. Understory vegetation cover at these sites is generally sparse. Populations generally occur on moderate slopes and southerly aspects are most common.

Allotropia virgata is obligately dependent on an association with a mycorrhizal fungus which in turn is associated with a tree, likely lodgepole pine (Pinus contorta) or Douglas-fir (Pseudotsuga menziesii). It is thus, highly sensitive to the loss of these canopy trees whether through timber harvest or stand-replacing fire. Several of the current locations of Allotropia virgata are within proposed timber sales.

Populations of Allotropia virgata are characteristically small with most being fewer than 100 stalks. Many populations consist of fewer than 5 stalks. These small populations are often scattered across the landscape in large areas of seemingly suitable habitat. This suggests that the habitat requirements of the species are quite specific and may relate to the occurrence of a suitable fungal partner.

Management planning should take all Montana sites into account in order to maintain viable populations. Field surveys should be continued for additional populations on the Beaverhead, Bitterroot and Deerlodge National Forests. Monitoring of existing populations should be continued and expanded. Additionally, the information gathered in the survey and monitoring activities recommended above should be used to prepare a species management guide for Allotropia virgata. The guide should be prepared in cooperation with the Nez Perce National Forest and the Idaho Conservation Data Center and should include the Idaho populations in the strategy.

II. SPECIES INFORMATION

A. CLASSIFICATION

1. **SCIENTIFIC NAME:** Allotropia virgata T. & G. ex Gray
2. **COMMON NAME:** candystick, sugarstick (Hitchcock et al. 1959).
3. **FAMILY:** Ericaceae (Heath Family).
4. **GENUS:** Allotropia virgata is the only member of this monotypic genus (Wallace 1975).
5. **SPECIES:** Allotropia virgata was first collected by the Wilkes Expedition in the Cascade Mountains of Washington in the late 1800's (Hitchcock et al. 1959). The first collection in Montana (Stickney (100b), MRC) was from the Bitterroot Mountains, St. Mary Peak, Ravalli County in 1965. First records for Idaho were in Idaho County, Selway River valley (Habeck (2503), MRC) in 1972. Prior to this, A. virgata was known only from California to British Columbia at low elevations in the Sierra Nevada, Cascade Mountains, and Coast Ranges (Steele and Stickney 1974).

B. PRESENT LEGAL OR OTHER FORMAL STATUS

1. FEDERAL STATUS

- a. **U.S. FISH AND WILDLIFE SERVICE:** None.
- b. **U.S. FOREST SERVICE:** Allotropia virgata is currently on the sensitive plant species list of Regions 1 and 4 of the U.S. Forest Service. Agency objectives and policy in the 1984 Forest Service Manual provide for the management and protection of sensitive species (Section 2670.32). Under these guidelines, the U.S. Forest Service is to "avoid or minimize impacts to species whose viability has been identified as a concern" (2670.32.2).

2. STATES:

Globally, this species is ranked by the Idaho Natural Heritage Program as "apparently secure = G4, although it may be quite rare in parts of its range, especially at the periphery" (Moseley and Groves 1990).

Montana: Allotropia virgata is currently ranked as critically imperiled in Montana (state rank S1 = 5 or fewer occurrences) (Achuff 1991). Survey work in 1991 found 11 new, large populations for a total of 27 populations. The state rank will be revised to S3 (21-100 occurrences).

Idaho: This species is on the monitor list in Idaho where it is ranked as a State Priority 2 species (Moseley and Groves 1990), "taxa likely to be classified as Priority 1 within the foreseeable future in Idaho, if factors contributing to their population decline or habitat degradation or loss continue." It is currently known from about 45 locations in the state, all in Idaho County (Lichthardt and Mancuso 1991).

C. DESCRIPTION

1. **GENERAL NONTECHNICAL DESCRIPTION:** Allotropia virgata is a striking plant, most notable for the thick reddish-brown and off-white candy-striped stems that are up to ca. 15.5 inches (40 cm) tall. It lacks green coloration. Single stems or clusters of stems arise from deep-seated, branching roots. The unbranched stems bear numerous flowers near the top. Flowers face away from the stem but do not droop and each is composed of 5 sepals that are white to pinkish or brown. Stems from previous years are often present. These are dark reddish-brown and often hollow (Lichthardt and Mancuso 1991, Hitchcock et al. 1959)
2. **TECHNICAL DESCRIPTION:** Achlorophyllous, simple-stemmed herbs with single to numerous stems from a diffuse, deep-seated root system with branch roots and adventitious buds at intervals along its length. Plants 10-40 cm tall, stems white and pink-striped, 5-10 mm thick; leaves linear-lanceolate; flowers in terminal spikelike racemes, 5-20 cm long, axillary and exceeded by the subtending bract, often with 1-2 bracteoles below the calyx; sepals 5, distinct, white or pinkish to brownish, ca. 5 mm long; corolla lacking; stamens 10, without appendages, purplish, opening by basal (falsely terminal) pores, from about equal to twice as long as the sepals; pistil 5-carpellary, styles very short, stigma shallowly 5-lobed; ovary superior, 5-celled, with axile placentation; fruit a capsule (Hitchcock et al. 1959)
3. **LOCAL FIELD CHARACTERS:** Allotropia virgata is distinguished from other achlorophyllous members of the Ericaceae by longitudinally pink and white-striped

stems and the lack of a true corolla. It often occurs with, but is easily distinguished from, Hypopitys monotropa which usually has a four-merous perianth, anthers that open by a continuous full-length slit across the top, and stems that are white, yellowish or pinkish. Pterospora andromedea also occurs with A. virgata, but differs by being usually taller (ca. 11.5-39 inches (30-100 cm)), with five sepals and an urn-shaped (connate) five-lobed corolla that is pendulous, with bracts along the stem that are much reduced, and with anthers that are awned on the back.

D. GEOGRAPHICAL DISTRIBUTION

1. **RANGE:** Allotropia virgata is known from southwestern British Columbia and south through the Cascades, on both the east and west sides, into the Sierra Nevada and Coast Ranges of California (Hitchcock et al. 1959). It is disjunct in east-central Idaho (Idaho County) and western Montana (Ravalli, Granite and Beaverhead counties) where it is one of several species that have coastal affinities and a similar disjunct pattern (Lorain 1988).
2. **CURRENT SITES:** In Montana, it is currently known from 27 populations in Ravalli, Granite and Beaverhead counties. Prior to the 1991 field season, A. virgata was known from 16 locations, only three of which contained more than a few plants. In 1991, surveys conducted by personnel of the Lolo and Bitterroot national forests and the Montana Natural Heritage Program located nine more populations, many of which contained up to several hundred individual plants.
3. **HISTORICAL SITES:** Several populations were last observed in the mid-1970's but none should be considered historical.
4. **UNVERIFIED/UNDOCUMENTED REPORTS:** None.
5. **AREAS SURVEYED BUT SPECIES NOT LOCATED:**

Bitterroot National Forest

E. HABITAT

1. **DESCRIPTION:** In Montana, Allotropa virgata populations occur most often in Abies lasiocarpa/Xerophyllum tenax or Abies lasiocarpa/Vaccinium scoparium habitat types. The dominant canopy tree is usually Pinus contorta with Pseudotsuga menziesii often co-dominant; Tree cover is commonly 40-50%. The cover of Abies lasiocarpa is usually low and plants are often at the sapling or seedling stage. Stand age is 120-330 years with an average of about 200 years. Understory vegetation cover at these sites is generally sparse with shrub cover typically 30% and herbaceous cover 10-15%. Populations generally occur on moderate slopes of 15-25% and on all aspects, although southerly aspects are most common. Many sites have been lightly burned as evidenced by fire scars on canopy trees.
2. **ASSOCIATED SPECIES:** The following plant species are commonly associated with Allotropa virgata:
 - Abies lasiocarpa (subalpine fir)
 - Pinus albicaulis (whitebark pine)
 - Pinus contorta (lodgepole pine)
 - Pseudotsuga menziesii (Douglas fir)
 - Amelanchier alnifolia (western serviceberry)
 - Arctostaphylos uva-ursi (kinnikinnick)
 - Arenaria macrophylla (bigleaf sandwort)
 - Arenaria rubella (reddish sandwort)
 - Arnica cordifolia (heart-leaf arnica)

Arnica latifolia (broadleaf arnica)
Calamagrostis rubescens (pinegrass)
Calamagrostis tweedyi (Cascade reedgrass)
Carex concinna (low northern sedge)
Carex concinnoides (northwestern sedge)
Carex geyeri (elk sedge)
Chimaphila umbellata (common prince's pine)
Chimaphila menziesii (little prince's pine)
Epilobium angustifolium (fireweed)
Festuca idahoensis (Idaho fescue)
Fragaria virginiana (common strawberry)
Goodyera oblongifolia (western rattlesnake-plantain)
Hedysarum occidentale (western hedysarum)
Hieracium albiflorum (white-flowered hawkweed)
Hypopitys monotropa (fringed pinesap)
Lonicera utahensis (Utah honeysuckle)
Menziesia ferruginea (false huckleberry)
Pedicularis contorta (coiled-beak lousewort)
Pedicularis racemosa (sickle-top lousewort)
Phlox longifolia (long-leaved phlox)
Pterospora andromedea (woodland pinedrops)
Pyrola asarifolia (pink wintergreen)
Pyrola picta (white-vein pyrola)
Ribes americanum (black current)
Salix scouleriana (Scouler willow)
Sedum lanceolatum (lance-leaved stonecrop)
Spiraea betulifolia (shiny-leaf spiraea)
Vaccinium globulare (globe huckleberry)
Vaccinium membranaceum (big huckleberry)
Vaccinium scoparium (whortleberry)
Viola orbiculata (round-leaved violet)
Xerophyllum tenax (beargrass)

3. **SOIL RELATIONSHIPS:** The sites are all on soils derived from the granitic parent materials of the Idaho batholith. These soils are probably acidic but no analyses have been done.

F. POPULATION DEMOGRAPHY AND BIOLOGY

1. **PHENOLOGY:** Annual, elongated, spike-like stems arise from a perennial root mass in late June or early July and persist, often for more than a year, after the stem has died.
2. **POPULATION SIZE AND CONDITION:** The populations of Allotropa virgata are characteristically small with most being fewer than 100 ramets. Many locations consist of fewer than 5 plants. Occasionally, populations have several hundred ramets. These small populations are often scattered across the landscape in large areas of seemingly suitable habitat. This

suggests that the habitat requirements of the species are quite specific and may relate to the occurrence of a suitable mycobiont.

3. REPRODUCTIVE BIOLOGY

- a. **TYPE OF REPRODUCTION:** Sexual.
- b. **POLLINATION BIOLOGY:** Nectar accumulates by adhesion in the small spaces bounded by the ovary and the sepals. Bumblebees are the primary known pollinators, Psithyrus insularis and Bombus mixtus. Often there is more than one floral axis per root mass and more than several flowers per axis which constitutes a significant reward for pollinators (Wallace 1977).

G. POPULATION ECOLOGY

1. BIOLOGICAL INTERACTIONS

- a. **EPIPARASITISM:** Allotropa virgata indirectly parasitizes pines and perhaps Douglas-fir via connecting mycelia of mycorrhizal fungi. This epiparasitism is relatively common in the plant kingdom, occurring in at least 7 families, 51 genera, and approximately 400 species (Furman and Trappe 1971). Studies of Monotropa and Hypopitys show that they are unable to survive without a fungal associate (Furman and Trappe 1971). They are best regarded as highly specialized and are the most dependent component of an anatomically-linked system of interacting plants. Materials move from the green component to the achlorophyllous component and vice versa (Furman and Trappe 1971). This is likely true for A. virgata as well.
- a. **COMPETITION:** In Montana, A. virgata does not occur often in areas with a high percentage of understory cover. It obviously does not compete for light but may be affected by competition for water or soil nutrients, although it derives much of these from the photosynthetic tree and mycorrhizal fungus.
- b. **HERBIVORY:** Grazing of A. virgata stalks by large ungulates has been observed.

III. ASSESSMENT AND MANAGEMENT RECOMMENDATIONS

A. THREATS TO CURRENTLY KNOWN POPULATIONS:

1. **GRAZING:** The sites occupied by Allotropa virgata contain very small amounts of forage and thus it is unlikely that grazing would have much effect on this species. Casual observation suggests that some

Allotropia virgata plants may have been browsed by ungulates but the significance of this is unclear.

2. **TIMBER HARVESTING:** Several of the current locations of Allotropia virgata are within proposed timber sales. Since Allotropia virgata is dependent, through an intervening fungus, on the continued existence of living canopy trees, timber harvest is a serious to the plant.
- B. **MANAGEMENT PRACTICES AND RESPONSE:** Removal of trees, either by harvesting or stand-replacing fire, upon which Allotropia virgata is dependent would likely result in a loss of populations, since other mycotrophic species have been observed to recede from the edges of logged or burned areas (Castellano 1990). Allotropia virgata would likely survive less severe fires that leave the canopy trees essentially intact because it has a deep-seated rootstock.
- C. **RECOMMENDATIONS FOR MAINTAINING VIABLE POPULATIONS:** The following recommendations are made to ensure that the long-term viability of Allotropia virgata populations is maintained on U.S. Forest Service land in Montana.
1. Protection of natural habitats that currently support Allotropia virgata populations. Management plans on the Bitterroot and Deerlodge National Forests should take all known populations into consideration and prevent disturbance of the sites.
 2. Notification of U.S. Forest Service personnel of sites on U.S. Forest Service lands. To prevent inadvertent impacts on currently known sites, personnel involved in planning activities should be provided with detailed information on the location of Allotropia virgata populations. It is especially important that timber sale managers and engineers at the Ranger District level know of these locations so that disturbance can be prevented.
- D. **RECOMMENDATIONS FOR FURTHER ASSESSMENT:**
1. Further field surveys of potential habitats. Surveys in 1991 located additional populations in both Montana (section V) and Idaho (Lichthardt and Mancuso 1991). Additional surveys should be made in portions of the Beaverhead, Bitterroot, and Deerlodge National Forests.
 2. Establish and continue monitoring studies to assess population condition and status. Several monitoring

sites were established in 1991. Monitoring of these sites should be continued in 1992 and additional sites should be established.

3. **Prepare a species management guide (conservation strategy).** The information gathered in the survey and monitoring activities recommended above should be used to prepare a species management guide for Allotropa virgata. The guide should be prepared in cooperation with the Nez Perce National Forest and the Idaho Conservation Data Center and should include the Idaho populations in the strategy. Challenge Cost-Share projects have been proposed by the Montana Natural Heritage Program with the Beaverhead, Bitterroot and Deerlodge National Forests for 1992 to further the above recommendations.
